

UHealth Launches Opioid Use Disorder Program in Primary Care Clinics

A new opioid use disorder program is now available through primary care clinics at UHealth – the University of Miami Health System.

Patients receive confidential medication-assisted treatment and are connected with UHealth specialty care providers, and other health and social services as needed.

“We now offer a medication-assisted treatment program that has shown to be highly effective in treating opioid addictions,” said Viviana E. Horigian, M.D., associate professor of public health sciences and researcher in the Department of Public Health Sciences at UM’s Miller School of Medicine.

The Miller School’s Department of Family Medicine and the Department of Medicine’s Division of Internal Medicine

recently implemented an Office-Based Addiction Treatment (OBAT) program at two primary care clinics at the Professional Arts Center on the medical campus.

“Patients can now be seen in a primary care setting that offers state-of-the-art medical treatment rather than going to a specialized substance-abuse facility,” Dr. Horigian said. “It is more convenient for patients and removes the potential stigma when dealing with an opioid addiction.”

The UHealth OBAT team’s dedicated medical professionals specialize in the treatment of opiate use disorder. A nurse care manager oversees a patient’s opiate use disorder in the same way other chronic health conditions are managed in primary care. Patients receive confidential medication-assisted treatment with buprenorphine or naltrexone and are connected with UHealth specialty care providers and other health and social services as needed.

“Our program, which is supported by a federal grant, is designed to meet an important public health need in our community,” said Dr. Horigian, who applied and received the grant for UHealth. “Nationally, only 10 percent of individuals with opioid use disorder are receiving treatment, so increasing access through primary care clinics is an important step forward in addressing the opioid epidemic.”

Dr. Horigian has long been an advocate for better national surveillance and reporting on the national opioid epidemic, which claims about 175 lives every day. Expanding access to medication-assisted treatment and risk-reduction programs, such as clean syringe exchange programs, can play an important role in reducing the death toll.

The UHealth program is based on the Massachusetts Model developed by Boston Medical Center in the early 2000s. This nationally recognized OBAT program serves as a model for facilitating access to lifesaving treatment and improving treatment outcomes in patients with opioid use disorders.
